

OBJECT PERMANENCE UNDER ROBOT SELF-OCCLUSION: A FROZEN MUJoCo NEGATIVE RESULT

Anonymous authors

Paper under double-blind review

ABSTRACT

Robots often hide task-relevant objects with their own bodies, grippers, or tools. This paper asks whether explicit robot self-occlusion geometry is a necessary object-permanence mechanism for closed-loop manipulation, or whether strong learned and filtering baselines already extract the useful signal. We rebuild the original short near-miss report into a frozen MuJoCo benchmark with 10,080 main method-evaluation rows, 1,536 ablation rows, 4,320 stress rows, 1,680 seed summaries, 195 paired comparisons, and 12 negative cases. The benchmark includes long self-occlusions, end-effector occlusions, distractor swaps, near-identical distractors, hidden contact drift, false reappearance, camera dropout bursts, stale-memory traps, embodiment-control shift, high-symmetry layouts, combined stress, and combined extreme stress. The result is negative. On hard regimes, occlusion-aware permanence v5 reaches 0.929 success, while the strongest non-oracle baseline, occlusion aware permanence v4, reaches 0.908. On combined and extreme regimes, occlusion-aware permanence v5 reaches 0.719 while occlusion aware permanence v4 reaches 0.740. At a fixed 10 percent failure budget, occlusion-aware permanence v5 reaches 0.000 while random forest occlusion regressor reaches 0.933. The frozen terminal decision is **KILL ARCHIVE**. We archive the result because explicit self-occlusion geometry is plausible, useful in some regimes, and still not isolated as the necessary mechanism under hostile review.

1 QUESTION

Object permanence is an intuitive requirement for robot manipulation: a target should not disappear from the robot’s state merely because the robot hid it. The tempting claim is that robot self-occlusion should be modeled as a special physical event rather than as generic missing observations. The stronger ICLR-main claim is harder. It requires showing that a self-occlusion mechanism beats Kalman-style filtering (Kalman, 1960), particle belief tracking (Gordon et al., 1993; Thrun et al., 2005), learned hidden-state predictors (Breiman, 2001; Pedregosa et al., 2011), and object-centric manipulation baselines (Min & Kim, 2025; Ren et al., 2024; Daniel et al., 2026).

The old Paper 71 result was a near miss. The proposed method was ahead in mean combined-stress success, but the paired interval crossed zero and the no-self-mask ablation stayed close. This version is therefore not a polishing pass. It is an adversarial rebuild. The benchmark is enlarged, the baselines are strengthened, the ablations are made more hostile, and the final protocol is frozen before the full run. If the self-occlusion mechanism fails, the paper is killed honestly.

2 PROBLEM SETUP

Each episode contains a robot tool state x_t , a target object o_t , a distractor object d_t , and an observation y_t from a fixed camera. The observation can be missing because the target is outside the visibility model, dropped by the camera, or hidden by the robot’s own swept segment. Let $m_t \in \{0, 1\}$ indicate self-occlusion by the robot geometry, and let f_t indicate a false distractor de-

tection. A method maintains a belief b_t and selects a tool target u_t . The closed-loop task succeeds if the tool reaches the true target and avoids committing to the distractor.

The key distinction is that self-occlusion is not arbitrary missingness. When $m_t = 1$, the robot has privileged kinematic evidence that the target may still be behind its own body. However, this does not automatically justify a new mechanism. A learned regressor or particle filter can also learn the same conditional structure if the benchmark exposes enough regularity. This is the core falsification pressure.

Metrics. We report closed-loop success, false disappearance, wrong-object contact, identity switch rate, mean localization error during occlusion, reacquisition latency, diagnostic steps, calibration error, fixed-risk success, stress-sweep performance, paired seed differences, ablations, and negative cases. False disappearance is counted when belief uncertainty exceeds the deployment threshold during occlusion. Identity switch is counted when the belief is pulled closer to the distractor after a false detection.

3 METHOD UNDER TEST

occlusion-aware permanence v5 keeps a branch belief over hidden target hypotheses. One branch follows the previous belief and velocity; another branch uses a learned hidden-state predictor; a third branch is damped by the self-occlusion geometry and contact-drift model. False detections are rejected when they are inconsistent with the self-mask and recent identity trace. During high uncertainty, the method may take a diagnostic viewing motion rather than greedily reaching.

This object is deliberately modest. It is not a deep video model, not a foundation policy, and not a claim about all object permanence. It tests whether explicit robot self-occlusion geometry is needed in a controlled manipulation setting. The implementation is CPU-only and uses MuJoCo for deterministic physics (Todorov et al., 2012).

4 BASELINES

The comparison set is designed to make the proposed mechanism uncomfortable. It includes last-seen memory; visibility-gated Kalman filtering; particle belief tracking; a polynomial ridge hidden-state predictor; random forest and histogram-gradient hidden-state regressors; identity-consistency tracking; an ensemble uncertainty planner; a risk-averse particle planner; a lightweight POMDP-style belief planner inspired by manipulation under object uncertainty (Pajarinen et al., 2023); the original v4 mechanism; a no-self-mask ablation; and an oracle true-state upper bound.

The learned baselines are important. If a random forest or histogram-gradient model can infer the target under occlusion from the same compact features, then the explicit branch mechanism is not isolated. Similarly, if the v4 replay matches or beats v5, the new components are not justified.

5 FROZEN PROTOCOL

The full run was frozen in docs/paper71_protocol_freeze_20260621.md. It uses 8 seeds, 6 main episodes per seed/split, 15 main splits, 14 main methods, 4 ablation splits, 12 ablation methods, 3 stress splits, 5 stress levels, and 12 stress methods. No gate was changed after the development probe.

The frozen gates are: the hard-regime success margin must exceed the strongest non-oracle baseline by 0.030; the paired lower bound against the strongest combined/extreme baseline must be positive; the combined/extreme success margin must exceed 0.030; false disappearance and wrong-object contact cannot regress by more than 0.020; fixed-risk success at a 10 percent failure budget cannot be worse than the best baseline; maximum-stress success must be within 0.030 of the best non-oracle method; and every removed-component ablation must fall at least 0.020 success below full v5 or be clearly worse on safety/calibration.

Table 1: hard splits aggregate results. Higher success is better; lower failure metrics are better.

6 MAIN RESULTS

The hard-regime aggregate shows why the result is a near miss rather than a win. occlusion-aware permanence v5 is useful: it reaches 0.929 success. But the strongest non-oracle baseline, occlusion aware permanence v4, reaches 0.908. That is not enough separation for a submission claim under the frozen margin. The mechanism is plausible, yet the experiment does not show it is necessary.

The combined/extreme aggregate is more damaging. occlusion-aware permanence v5 reaches 0.719, while occlusion aware permanence v4 reaches 0.740. This matters because the intended contribution is robustness under hard self-occlusion, not nominal visible reaching. When stress combines false reappearance, hidden drift, near-identical distractors, and control limits, the v4 replay remains too competitive.

7 FIXED-RISK ANALYSIS

A method that wins by tolerating false disappearance or identity switches is not deployable. The fixed-risk table therefore asks how much success remains when the maximum failure budget is fixed at 10 percent over hard splits. occlusion-aware permanence v5 reaches 0.000, while random forest occlusion regressor reaches 0.933. This is a fatal gate: the explicit self-occlusion mechanism cannot claim safer object permanence if a learned baseline occupies the safer operating point.

8 STRESS SWEEP

Stress sweeps increase occlusion width, dropout, camera noise, false detections, hidden drift, and control limits. They test whether the method degrades gracefully as the self-occlusion story becomes most relevant. The maximum-stress gate does not rescue v5. Even when the qualitative story fits the setting, the frozen result says the mechanism is not isolated strongly enough.

Table 3: Selected methods on combined extreme stress.

Method	Success	False disp.	Wrong obj.	Id switch	Occ. err.

no self mask ablation	0.000	0.000	1.000	1.000	1.000

9 ABLATIONS

The ablation table is the most direct mechanism test. Full v5 is not cleanly separated from removals of branch belief, distractor filtering, false-detection rejection, reacquisition guard, tail-risk objective, or uncertainty inflation. Some removals improve success or remove false disappearance without enough compensating harm. That means the branch story is not established by the benchmark.

10 NEGATIVE CASES

The negative cases are not outliers to hide. They expose the scientific failure modes: hidden displacement can exceed the branch update; false reappearance can compete with target permanence; prolonged stale memory can remain confident in the wrong place; and identity switches can occur before the diagnostic motion recovers visibility. These are precisely the cases a submission would need to solve.

11 THEORY: WHEN SELF-OCCLUSION GEOMETRY HELPS

Proposition 1: self-mask informativeness. Let Y_t be the camera observation and M_t the known robot self-occlusion event. If $P(Y_t = \emptyset \mid M_t = 1, o_t = o)$ differs across object hypotheses only through the known robot geometry, then a belief update that conditions on M_t can reduce posterior entropy relative to a missing-at-random filter. This supports the intuition behind v5.

Proposition 2: learned-baseline non-identifiability. If the feature vector supplied to a learned baseline contains the same last-visible state, tool state, occlusion age, noise level, false-detection flag, and drift proxy used by the explicit branch mechanism, then a sufficiently flexible regressor can approximate the branch posterior mean on the benchmark distribution. In that case, a local benchmark cannot identify the explicit branch object as necessary unless v5 beats the learned baseline under held-out stress and safety gates. This is the failure observed here.

Proposition 3: ablation necessity. Let M be full v5 and M_{-j} remove component j . If $S(M) - S(M_{-j}) < \delta$ and M_{-j} is not worse on false disappearance, wrong-object contact, identity switch,

or calibration, then component j is not locally supported. The frozen ablation table violates this condition for several components.

12 RELATED WORK

This paper sits between probabilistic tracking, partial-observability planning, and object-centric robot world models. Kalman and particle filters remain strong baselines for occluded state estimation (Kalman, 1960; Gordon et al., 1993; Thrun et al., 2005). Robot manipulation under object uncertainty motivates belief-space and POMDP-style baselines (Pajarinen et al., 2023). Object-centric and scene-graph systems provide broader context for maintaining persistent object state in manipulation and navigation (Min & Kim, 2025; Loo et al., 2025; Honerkamp et al., 2024; Ren et al., 2024; Liu et al., 2026; Daniel et al., 2026). Visuo-haptic and keypoint approaches show that

Figure 2: False disappearance by split. This is a safety-relevant failure mode, not just a tracking diagnostic.

Figure 3: Stress sweep success. The frozen maximum-stress gate is applied before seeing the final result.

occluded object state can also be recovered through learned or multimodal representation (Rustler et al., 2023; von Hartz et al., 2022). This work does not beat those families; it creates a controlled negative audit of one explicit self-occlusion mechanism.

13 DECISION

The frozen terminal reason is:

v5 does not beat strongest hard-regime baseline occlusion_aware_permanence_v4 by 0.030 (v5=0.929, best=0.908); paired lower bound against occlusion_aware_permanence_v4 is not positive (-0.042+/-0.135); v5 does not beat strongest combined/extreme baseline occlusion_aware_permanence_v4 by 0.030 (v5=0.719, best=0.740); fixed-risk gate fails at budget 0.10 (v5=0.000, best=random_forest_occlusion_regressor 0.933); ablation gate fails because ablate_no_branch_belief, ablate_no_distractor_filter, ablate_no_false_detection_rejection, ablate_no_reacquisition_guard, ablate_no_tail_risk_objective, ablate_no_uncertainty_inflation matches or beats full v5

Table 6: Occlusion-aware permanence v5 ablations aggregated over frozen ablation splits.

Ablation	Success	False disp.	Wrong obj.	Id switch	Occ. err.
ablate no reacquisition guard	0.906	0.524	0.000	0.040	0.049
ablate no false detection rejection	0.891	0.529	0.000	0.063	0.051
ablate no tail risk objective	0.891	0.521	0.008	0.033	0.052
ablate no uncertainty inflation	0.867	0.000	0.000	0.052	0.050
occlusion full v5	0.867	0.528	0.000	0.026	0.052
ablate no branch belief	0.852	0.523	0.000	0.072	0.052
ablate no distractor filter	0.852	0.529	0.000	0.082	0.053
occlusion aware permanence v4	0.844	0.616	0.000	0.018	0.051
ablate no identity filter	0.820	0.614	0.000	0.067	0.051
learned only branch	0.812	0.228	0.000	0.040	0.057
ablate no self mask	0.805	0.661	0.000	0.057	0.067
ablate no contact update	0.773	0.526	0.000	0.031	0.057

Figure 4: Ablation success over frozen hard ablation splits. The method fails the component-necessity gate.

The correct decision is **KILL_ARCHIVE**. This is not a writing failure. It is a scientific result: explicit self-occlusion permanence is a plausible mechanism, but this benchmark does not prove it is necessary over strong learned, v4 replay, and ablated baselines.
